The process of liberation from mechanical ventilation is becoming more standardized, with evidence supporting daily trials of spontaneous breathing in all suitable mechanically ventilated patients. This article critically reviews the most important recent advances in mechanical ventilation and suggests future directions for further research in the field.

Recent advances in mechanical ventilation.

Important advances have been made over the past decade towards understanding the optimal approach to ventilating patients with acute respiratory failure. Evidence now supports the use of noninvasive positive pressure ventilation in selected patients with hypercapnic respiratory failure and chronic obstructive pulmonary disease, cardiogenic pulmonary edema, and for facilitating the discontinuation of ventilatory support in patients with chronic pulmonary disease.

Mechanical ventilation is a cornerstone in the management of patients with acute respiratory distress syndrome (ARDS). We now know that mechanical ventilation per se can aggravate lung injury, a process referred to as ventilator-induced lung injury (VILI), through several mechanisms including volutrauma, barotrauma and biotrauma [1-4]. Dynamic lung distension and repeated opening and closing of recruitable lung units are considered the two main mechanisms contributing to lung injury.

Mechanical Ventilation is one of the most important topics in medical education especially for Doctors and Respiratory Therapists and stands to be a corner stone in emergency departments. Originally , only respiratory therapists used to acquire knowledge on mechanical ventilation. But, now a days, due to increase in the respiratory infections and life threatening diseases, knowledge about ventilation and ventilators have been extended beyond respiratory therapists i.e., all the life ...
