A protein kinase inhibitor is a type of enzyme inhibitor that blocks the action of one or more protein kinases. Protein kinases are enzymes that add a phosphate group to a protein, and can modulate its function. The phosphate groups are usually added to serine, threonine, or tyrosine amino acids on the protein: most kinases act on both serine and threonine, the tyrosine kinases act on tyrosine, and a number act on all three. There are also protein kinases that phosphorylate other amino acids, in

Protein kinase inhibitor - Wikipedia

Polycyclic aromatics, such as isoquinolinesulfonyl and naphthalenesulfonyl compounds (\square H-series \square) and naturally occurring molecules, such as staurosporine analogs (\square K-series \square) have served primarily as valuable inhibitors of AGC-type protein kinases, notably PKC [22, 24, 47-51]. In fact, the inhibitory potency against PKC is a defining property of most ATP-site inhibitors of the above series.

Classical Type I inhibitors bind reversibly to the ATP-binding pocket of protein kinases and exhibit steady-state enzyme competitive inhibition with respect to ATP. Of importance, Type I inhibitors do not require specific spatial arrangements of the α C-helix or the DFG-Asp for their effectiveness and they are able to bind to active and inactive enzyme forms.

To date, the majority of clinical and preclinical kinase inhibitors are ATP competitive, noncovalent inhibitors that achieve selectivity through recognition of unique features of particular protein kinases.

Developing Irreversible Inhibitors of the Protein Kinase ...

However, the structural conservation of protein kinase ATP binding sites and the presence of more than 500 protein kinases in the human genome 2 led to the belief that highly selective small-molecule protein kinase inhibitors targeting the ATP pocket would be difficult to generate.

Medicinal chemists can classify kinase inhibitors by how they work at the molecular level. Type I is \square a small molecule that binds to the active conformation of a kinase in the ATP pocket, \square Type II is \square a small molecule that binds to an inactive (usually Asp-Phe-Gly (DFG)-OUT) confirmation of a kinase, \square and the type III inhibitor as \square a non-ATP competitive inhibitor \square or allosteric inhibitor

Over 30 kinase inhibitors are approved in the US for cancer treatment with more under development. Of the 52 new drugs approved by the FDA for cancer from 2015 to 2019, 16 were kinase inhibitors. This is one of the most active areas of medical chemistry research. Protein enzymes are chains of amino acids and when a phosphoryl group, PO_3^{2-} , is covalently attached to one of the amino acids, it changes the three-dimensional configuration and function of the protein.

Kinase Inhibitors for Cancer Treatment

mTOR inhibitors are a class of drugs that inhibit the mammalian target of rapamycin (mTOR), which is a serine/threonine-specific protein kinase that belongs to the family of phosphatidylinositol-3 kinase (PI3K) related kinases (PIKKs). mTOR regulates cellular metabolism, growth, and proliferation by forming and signaling through two protein complexes,

Inhibitors of p21-activated kinases (PAKs)

Because protein kinases undergo dramatic conformational reorganization, as well as being catalytically active, the precise architecture of these structural changes is important in the function of inhibitors. So called type I inhibitors bind competitively with ATP to the hinge region, displacing ATP, and preventing catalysis.

Identification of inhibitors of the kinase activities of CLK and SRPK family members. To identify inhibitors of splicing-related kinases, high-throughput screening was conducted with 870,000 compounds at a single concentration of 1 μ M in luminescent in vitro kinase assays using SRPK1. A total of 319 active compounds satisfied the criteria to inhibit 30% of SRPK1 enzyme activity.

Bivalent inhibitors of protein kinases can be separated into two groups depending on the interactions that they make with their kinase target. Bisubstrate kinase inhibitors are composed of an ATP-competitive ligand covalently tethered through a linker to a pseudosubstrate peptide of the protein kinase of interest.

A protein kinase is a kinase which selectively modifies other proteins by covalently adding phosphates to them (phosphorylation) as opposed to kinases which modify lipids, carbohydrates, or other molecules. Phosphorylation usually results in a functional change of the target protein by changing enzyme activity, cellular location, or association with other proteins.
